VTI slow-branch check: isotropic control

Only epsilon and delta are changed to zero. Same Vp, density, source, grid, time step and PML.

Original VTI
epsilon > delta

Isotropic limit
epsilon = 0
delta = 0

Color: sV / A, signed-square-root mapping; shared A = 0.00049 Pa across both rows and all times. No clipping.

The central diamond-like slow branch is absent in the isotropic control. This supports its pseudo-acoustic qSV interpretation; it is not a modal projection of the original heterogeneous wavefield. The isotropic PDE has a zero slow eigenvalue.
